

can you tell me about the inner circle trader, smt and pd ar
give me a detailed explanation.

💡 Thought for 31s

The Inner Circle Trader (ICT) is a popular price-action trading methodology developed by **Michael Huddleston** (known online as "The Inner Circle Trader"). It focuses on how large institutions — referred to as "smart money" — manipulate and drive markets through liquidity grabs, order flow, and engineered price movements.

ICT is **not** based on indicators, lagging tools, or retail patterns. Instead, it teaches traders to read raw price structure, imbalances, and institutional footprints to trade *with* the banks rather than against them. These concepts apply mainly to forex (majors like EURUSD, GBPUSD), indices (NAS100, US30, ES/NQ), and crypto.

Key foundational ICT ideas include:

- **Market Structure:** Higher highs/higher lows (bullish) or lower highs/lower lows (bearish). Break of Structure (BOS) confirm trend continuation; Change of Character (CHoCH) or Market Structure Shift (MSS) signals potential reversals.
- **Liquidity:** Pools of stop-loss orders above highs (buy-side liquidity) or below lows (sell-side liquidity). Price often raids these areas before reversing.
- **Order Blocks (OBs):** Last opposing candle before a strong impulsive move (bullish OB = demand zone; bearish OB = supply zone).
- **Fair Value Gaps (FVGs):** Imbalances from fast moves (a 3-candle pattern where the middle candle creates a gap). Price tends to return to "fill" them.
- **Displacements:** Strong, one-sided candles that create voids and signal institutional aggression.
- **Kill Zones:** High-volatility trading windows (e.g., London open, New York open).

ICT models (like the 2022 Mentorship, Silver Bullet, Judas Swing, etc.) combine these into high-probability setups.

SMT (Smart Money Technique / Smart Money Divergence)

SMT stands for **Smart Money Technique** (sometimes called Smart Money Tools or Divergence in the trading community). It is one of the most powerful **confirmation tools** in ICT.

Core idea: Correlated assets (pairs or instruments that normally move together) should show *symmetrical* market structure. When they diverge (opposing highs/lows), it reveals **institutional manipulation** in one asset — the "deceptive" move that traps retail traders while smart money positions in the other.

How SMT Works

- **Positive correlation** (e.g., EURUSD & GBPUSD, ES & NQ, BTC & ETH): Assets usually make high highs/lower lows together.
- **Negative correlation** (e.g., EURUSD & DXY, gold & DXY): Assets move oppositely.

SMT Divergence occurs when symmetry breaks:

- One asset respects the expected high/low; the other does **not**.

forexbee.co

blog.opofinai

Bullish SMT Divergence (signals potential reversal higher / strength in the "weak" asset):

- Positive correlation example: Both pairs dropping → one makes a **lower low**, the other makes a **low**. The one making the lower low is manipulating (raiding sell-side liquidity), while the higher-asset shows real institutional buying.
- Negative correlation example: One makes a lower high while the other makes a lower low (instead of expected higher low).

Bearish SMT Divergence (signals potential reversal lower / weakness):

- Positive correlation: Both rising → one makes a **higher high**, the other makes a **lower high**.
- Negative correlation: One makes a higher low while the other makes a higher high (instead of expected lower high).

How traders use SMT:

- It is **never** a standalone entry signal.
- Use it to **confirm bias** when price reaches a higher-timeframe **PD Array**.
- Monitor on lower timeframes (≤ 15 -min) for precision.
- Strongest with highly correlated pairs (e.g., GBPUSD vs EURUSD, NAS100 vs SPX500, XAUUSD vs XAGUSD).

Example: Daily GBPUSD is at a premium PD Array (bearish bias). You see bearish SMT divergence vs EURUSD → this confirms institutions are likely selling GBP stronger → high-probability short setup

PD Arrays (Premium & Discount Arrays)

PD Arrays (Premium/Discount Arrays or "Premium and Discount Arrangement") are the **core frame** for trade execution in ICT. They organize all the other ICT tools (OBs, FVGs, breakers, etc.) into "cheap" or "expensive" price zones.

Definition: Price is divided using the **50% equilibrium** of a significant swing (old high to old low or vice versa).

- **Premium zone** = above 50% (expensive prices — institutions prefer to **sell** here).
- **Discount zone** = below 50% (cheap prices — institutions prefer to **buy** here).

You draw this with a Fibonacci retracement tool (levels: 1.0 → 0.5 → 0.0). The 0.5 level is equilibrium.

arongroups.co

arongr

PD Array Matrix / Checklist

The "array" refers to the **collection and hierarchy** of ICT tools sitting inside premium or discount zone. Higher-timeframe arrays carry more weight.

Common PD Array components (tools):

- Bullish/Bearish Order Blocks
- Bullish/Bearish Breaker Blocks
- Bullish/Bearish Mitigation Blocks
- Fair Value Gaps (BSI = buy-side imbalance; SBI = sell-side)
- Inversion FVGs
- Liquidity voids / Old highs/lows
- NDOG / NWOOG (New Day/Week Opening Gaps)
- Unicorn model, etc.

Bullish PD Array = multiple bullish tools clustered in the **discount** zone → look for **buys** when price and rejects one (after MSS upward).

Bearish PD Array = multiple bearish tools clustered in the **premium** zone → look for **sells**.

tradingfinder.com

How to use PD Arrays in practice (step-by-step):

1. On **higher timeframe** (daily/4H) → determine overall bias and locate the dealing range. Mark premium/discount with Fib.
2. If price has shifted structure bullish **and** is now in discount → daily bias = long.
3. Drop to **lower timeframe** (15-min or 5-min) after a Market Structure Shift.
4. Look for a **bearish PD Array in premium** (for shorts) or **bullish PD Array in discount** (for longs)
5. Wait for price to test/reject one of the arrays (e.g., a bullish OB in discount + FVG + liquidity raid)
6. Enter with confluence (SMT divergence, OTE Fib 61.8–78.6%, Kill Zone timing, etc.).
7. Target opposite liquidity or next PD Array.

PD Arrays answer the question: "**Where exactly should I buy low or sell high?**" Institutions buy in d and sell in premium to get the best possible price for their large orders.

How SMT and PD Arrays Work Together

The highest-probability setups in ICT combine both:

- Higher-timeframe PD Array gives the **location and bias**.
- SMT divergence gives the **confirmation** that smart money is actually manipulating in that direc
- Lower-timeframe PD Array + displacement/FVG gives the **precise entry**.

Important Notes

- ICT is **discretionary** — it requires screen time, backtesting, and journal work. There is no "plug-play" holy grail.
- Many free resources exist on YouTube (The Inner Circle Trader channel), innercircletrader.net, a community breakdowns.
- Like any methodology, results depend on the trader's execution, risk management (always use and psychology).

This is purely educational information based on publicly shared ICT concepts. Trading involves sub: risk of loss and is not suitable for everyone. Always do your own research and consider seeking adv from a qualified financial advisor.

If you'd like charts of specific setups, deeper dives into any single concept (e.g., Order Blocks, Silve model), or examples on a particular pair/index, just let me know!

what about the weekly prc

...

what about the weekly prc

💡 Thought for 49s

Weekly Profiles (also called **ICT Weekly Range Profiles** or **Weekly Bias Models**) are one of the mo powerful **contextual frameworks** in the Inner Circle Trader (ICT) methodology. They describe the **statistically recurring ways a trading week (Monday–Friday) typically unfolds** based on institutic manipulation and expansion.

Introduced in Michael Huddleston's original 2016–2017 mentorship (Month 7 – Short Term Trading), profiles help you:

- Predict **where the high or low of the week** is most likely to form.
- Determine **daily bias** with high confidence.
- Time when **PD Arrays** (premium/discount zones) will be raided or respected.
- Dramatically reduce over-trading by waiting for the profile to confirm.

They are **not** rigid predictions — they are probabilistic templates that work best when combined wi **Higher Timeframe (HTF) PD Arrays, Market Structure, SMT divergence**, and the economic calen

Core Mechanics of All Weekly Profiles

- **Manipulation Phase** (early week): Smart money induces retail traders by hovering around HTF Arrays without fully committing, raiding stops/liquidity.
- **Expansion Phase** (mid-to-late week): Strong directional move toward the opposite liquidity point next PD Array.
- **Key Anchor:** Always reference **HTF (Daily/4H) Premium or Discount PD Arrays** using the 50% equilibrium Fib.

en.rattibha.com

The Main Weekly Profiles (Simplified to the Most Common 3–5)

1. Classic Tuesday Low of the Week (Bullish Profile) – Highest probability classic expansion

- **Bias:** Overall bullish (price in or coming from HTF discount).
- **Monday:** Price hovers **above** HTF Discount Array (manipulation, no full raid).
- **Tuesday:** Strong displacement **down into** the Discount Array → forms **Low of the Week** (u London or NY open).
- **Wed–Fri:** Expansion higher (distribution).
- **How to anticipate:** If Monday fails to raid the discount array, Tuesday becomes the highest probability day for the weekly low.
- **Trading:** After Tuesday low + MSS bullish + SMT confirmation → buy lower-timeframe PD in discount.

en.rattibha.com

en.rattib

2. Classic Tuesday High of the Week (Bearish Profile) – Mirror image

- **Bias:** Overall bearish.

- **Monday:** Hovers **below** HTF Premium Array.
- **Tuesday:** Raids **up into** Premium Array → **High of the Week**.
- **Wed–Fri:** Expansion lower.
- Same timing logic as above.

forum.ictsharks.com

en.rattit

3. Wednesday Low/High of the Week

- Identical to the Classic Tuesday versions, but manipulation lasts through Tuesday → raid h on **Wednesday**.
- Slightly lower probability than Tuesday but very common when Tuesday is quiet.

4. Consolidation Thursday Reversal (Bullish or Bearish)

- **Mon–Wed:** Tight consolidation/range.
- **Thursday:** Final raid (low for bullish, high for bearish) + strong reversal (often news-driven, interest rate decisions ~2 PM NY time).
- Then powerful move into Friday opposite the raid.

5. Midweek Rally / Decline (Consolidation → Expansion)

- Early-week pause after already leaving a PD Array.
- No reversal candle → Thursday/Friday strong continuation toward the **opposite** HTF PD Ar

Low-probability profiles (avoid heavy trading):

- **Seek & Destroy Friday** (shallow liquidity grabs both sides then fakeout) — common in summer around NFP/ big news.

How Weekly Profiles + PD Arrays + SMT = Killer Confluence

1. **Weekly/Daily chart** → Mark HTF PD Arrays + determine broad bias.
2. **Sunday/Monday** → Watch which profile is developing based on Monday price action vs the PD
3. **Tuesday/Wednesday** → When the profile confirms (e.g., Tuesday low formed in bullish classic; in **daily/remaining-week bias**.
4. **Lower TF (15M/5M)** → After MSS + profile confirmation:
 - Wait for price to test a **lower-timeframe PD Array** in the direction of the weekly profile.
 - Confirm with **SMT divergence** on a correlated pair.
 - Enter during Kill Zone with displacement/FVG.
5. **Targets:** Opposite weekly liquidity or next higher PD Array.

Example (Bullish Classic Tuesday Low):

GBPUSD daily is in discount PD Array with bullish structure. Monday hovers above it. Tuesday Lond

strong bearish displacement into the array + SMT bullish divergence vs EURUSD. You buy the 15M b Order Block inside the discount → target weekly high liquidity. This is one of the cleanest high-prob setups in all of ICT.

Practical Tips

- These profiles come directly from ICT's original mentorship and repeat with high frequency across forex majors, indices (NAS100, US30), gold, and even BTC.
- Always cross-check the **economic calendar** — high-impact news can exaggerate or shift the price.
- Many traders use them purely for **bias**, not entries (e.g., "Tuesday low confirmed → only look for this week").
- There are slight variations across educators (some list 6–8 profiles), but the Classic Tuesday and Wednesday ones are the foundation.

Weekly Profiles turn PD Arrays from "static zones" into a **living weekly story** — they tell you *when* money is likely to raid them.

If you want me to:

- Break down a **specific profile** with more real-chart examples
- Show how it combines with the **Silver Bullet** or **Judas Swing**
- Analyze the **current week's profile** on a pair you trade
- Or give you the full 6-profile PDF-style summary

...just tell me. I can also walk you through marking these live on a chart.

This is all educational — trading carries risk of loss. Backtest heavily and journal your observations. Which pair or profile would you like to dive deeper into?

now what about the fractal behavior of all of this? since we have multiple timeframes, can't this be applied to any time frame?

💡 Thought for 28s

Yes — ICT is fundamentally fractal, and this is one of the most important (and often under-emphasized) pillars of the entire methodology.

Michael Huddleston repeatedly teaches that **"Time is fractal"** — the market prints the exact same logic, structure, liquidity behavior, and institutional manipulation on **every single timeframe** with complete autonomy. What happens on the monthly chart also happens on the 1-minute chart — just

compressed in time.

This fractal (self-similar) nature means **every single concept** we've discussed (PD Arrays, SMT, Wave Profiles, Order Blocks, FVGs, displacements, liquidity raids, BOS/CHoCH/MSS, Kill Zones, etc.) can be applied to **any timeframe** you choose.

What “Fractal Behavior” Actually Means in ICT

- The same price patterns repeat at every scale.
- A swing high/low on the weekly chart behaves identically (in logic) to a swing high/low on the 5 minute chart.
- A bullish Order Block in discount on the daily is the same concept as a bullish Order Block in discount on the 1-minute — only the holding time and range size differ.
- Institutional manipulation (inducement → raid → displacement → delivery) occurs on all time scales.

Here's a perfect visual of the fractal nature of market structure (swing highs/lows, breakers, etc.) across vastly different timeframes:

You can see the exact same logic (higher highs/higher lows, swing points) repeating on monthly → weekly → daily → hourly. That is fractal behavior.

PD Arrays Are Completely Fractal

Every timeframe has its own **independent PD Array** (50% equilibrium of its own significant swing).

- Higher-timeframe PD Arrays (weekly/daily) carry the **heaviest weight** and control the overall bias.
- Lower-timeframe PD Arrays (15M/5M/1M) sit **inside** the higher ones and give you precise entry points.

When multiple PD Arrays from different timeframes **align** (e.g., a daily bullish array inside a weekly discount + a 15M bullish OB inside that), confluence explodes.

Here's a real-chart example showing PD Arrays (Order Blocks, FVGs, etc.) overlapping across multiple timeframes on the same instrument:

medium.com

This is why ICT traders say: “One higher-timeframe range can contain infinite lower-timeframe setups.”

SMT Divergence Is Fractal

You can (and should) look for SMT on **any** timeframe:

- Daily SMT for swing bias
- 15M SMT for day-trade confirmation
- Even 1M SMT during Kill Zones for scalps

The logic never changes — only the speed and range.

Profiles Are Also Fractal

This is where it gets beautiful.

Weekly Profiles (Classic Tuesday Low/High, Wednesday reversal, Consolidation Thursday, etc.) have **direct fractal equivalents** on lower timeframes:

Weekly Concept	Fractal Equivalent on Lower TF	Typical Use Case
Classic Tuesday Low	Daily London Reversal (early low → NY expansion)	Day trading / scalping
Classic Tuesday High	Daily London Reversal Bearish	Day trading
Wednesday Low/High	Daily NY Reversal or NY Manipulation	Intraday
Consolidation Thursday	Session Seek & Destroy or tight Asian range → London/NY expansion	Any session

Here are clean visual examples of **Daily Profiles** (the fractal version of Weekly Profiles):

youtube.com

ttrades.com

blog.opofinai

You can even go smaller: 4H profiles, 1H profiles, or even “London session profiles” inside the day – manipulation → expansion logic.

How Traders Actually Use the Fractal Nature (Top-Down Approach)

1. **Highest TF** (Weekly/Daily) → Big-picture bias + major PD Arrays + Weekly Profile.
2. **Intermediate TF** (4H/1H) → Confirm structure shift (MSS) + next-level PD Arrays + Daily Profile
3. **Execution TF** (15M/5M/1M) → Wait for displacement + lower PD Array + SMT + Kill Zone.

This is exactly what the famous **ICT Fractal Model** (or “One Range, Infinite Setups”) teaches: shade higher-timeframe range, then hunt only the PD Arrays **inside** it on lower timeframes.

Practical Takeaways & Caveats

- **Yes** — you can trade pure 1-minute charts using full ICT (many scalpers do).
- **Yes** — you can swing trade using only weekly/monthly PD Arrays.
- Lower timeframes = more setups but **more noise** and tighter risk (spread/slippage matters more).
- Higher timeframes = fewer but higher-quality setups with wider stops.
- The magic happens in **confluence across fractals** — when the weekly, daily, and 15M all agree.

In short: ICT was designed to be **timeframe-agnostic** because the market itself is fractal. The tools change — only your holding period and risk parameters do.

If you want, I can:

- Show you a **live multi-timeframe breakdown** on a specific pair right now (tell me the pair).
- Dive deeper into the **Fractal Model** with more chart examples.
- Teach you how to “fractalize” a Weekly Profile down to a single trading session.

Just say the word. This fractal understanding is what separates traders who “get” ICT from those who collect concepts.

now tell me about the macro times? the 20 and. 50 min marks of hours? doesn't that tie into all of this ?

ICT Macro Times (often just called **Macros**) are **time-based algorithmic windows** where institutional/smart money algorithms are programmed to become more active — specifically to see liquidity, raid stops, fill **Fair Value Gaps (FVGs)**, reprice imbalances, or deliver directional moves. They add a **temporal layer** to the entire ICT framework, making setups even more precise by telling you **where** the market is most likely to move aggressively.

Michael Huddleston (ICT) introduced and expanded on these in his later mentorships (especially 2024 content), describing them as short "macro" commands the algo executes periodically.

Core Concept: The :50 to :10 Window (Your 20 and 50 Min Marks)

Yes — the **:20 and :50 marks** you mentioned tie directly into this. The most fundamental and recurring macro is the **20-minute window spanning the last 10 minutes of one hour and the first 10 minutes of the next**:

- **XX:50 – XX:10** (e.g., 09:50 – 10:10, 10:50 – 11:10, etc.)
 - Starts at the **:50 mark** (last 10 min of the hour).
 - Crosses the hour rollover.
 - Ends at the **:10 mark** (first 10 min of the new hour).

This creates a **~20-minute interval** (sometimes stretched to 20–30 min depending on context). ICT stated that **"ICT macro happens in every single hour"** containing this last-10 + first-10 structure — some exceptions or variations (like denser macros in the last hour of a session).

Why these exact marks?

- Algorithms often "reset" or spool up around hour changes (institutional order flow, fixings, etc.).
- The :50 mark frequently sees **manipulation/inducement** (false moves to grab liquidity).
- The :00 – :10 period is where **true displacement/expansion** often kicks in after the raid.
- This pattern repeats **every hour**, making it fractal (just like PD Arrays and profiles).

How Macros Tie Into Everything Else (Fractal & Confluence Layer)

Macros are **not** a standalone strategy — they're a **high-probability timing filter** that supercharges other ICT tools:

- **PD Arrays** → Wait for price to approach a premium/discount array, then look for entry/rejection specifically **during** a macro window (especially :50–:10).
- **Weekly/Daily Profiles** → Macros align with profile expansions (e.g., Tuesday Low often forms a classic NY AM macro like 09:50–10:10 or 10:50–11:10).
- **SMT Divergence** → Strongest when divergence appears or resolves **inside** a macro (confirms or negates manipulation).
- **FVGs & Order Blocks** → Macros are prime for **inversion FVGs**, liquidity sweeps, then displacement into/away from blocks.
- **Kill Zones** → Many macros overlap or nest inside Kill Zones (London Open, NY Open, NY AM). The classic NY AM macros (08:50–09:10, 09:50–10:10, 10:50–11:10) are especially powerful during the Kill Zone.
- **Fractal Nature** → Macros exist on **every timeframe** indirectly (e.g., a 5-min chart's "macro" mirrors a 20-min window scaled down), but they're primarily used on lower TFs (15M/5M/1M) for entries and to set bias on higher TFs.

Practical Use (Common Trader Flow):

1. Higher TF → Bias + PD Array location + Weekly Profile.
2. Drop to execution TF → Wait for price to reach PD Array.
3. Check time → If a **:50–:10 macro** is approaching/ongoing → probability spikes for sweep...

21 web pages

now tell me about the macro times? the 20 and. 50 min marks of hours? doesn't that tie into all of this ?

💡 Thought for 28s

Yes — Macro Times are the **precise temporal engine** that makes everything in ICT (PD Arrays, SMT Weekly/Daily Profiles, fractal behavior) come alive with **algorithmic timing**.

Michael Huddleston introduced and refined **Macros** (also called “Time Macros” or “Algorithmic Macros”) in his 2023–2024 mentorships as short, recurring windows where the institutional algorithms are explicitly programmed to **seek liquidity, reprice Fair Value Gaps, raid stops, or deliver displacement**. They are not random — they are scheduled “commands” the algo executes like clockwork.

The 20 & 50 Minute Marks You Asked About

This is the **core macro** in ICT:

- **Every single hour** has a **20-minute Macro Window**:
XX:50 → XX:10
 (last 10 minutes of the current hour + first 10 minutes of the next hour)

Examples (all times in **New York / EST** — adjust for your timezone):

- 08:50 – 09:10
- **09:50 – 10:10** ← the most famous one (especially for indices & Silver Bullet setups)
- 10:50 – 11:10
- 11:50 – 12:10 (Lunch macro)
- 13:50 – 14:10
- ...and so on, all day long

This is exactly the “20 and 50 min marks” you mentioned. The :50 mark is the trigger — price often becomes “algorithmic” right around then.

writofinance.com

time-price-research-astrofin.blogspot

Full List of Key Macro Windows (NY Time)

London Session Macros (earlier, lower volume but very clean):

- 02:33 – 03:00 (pre-London)
- 04:03 – 04:30 (London Open macro)

New York Session Macros (highest probability for most retail traders):

- 08:50 – 09:10 (NY Open macro)
- 09:50 – 10:10 (AM #2 — extremely powerful)

- 10:50 – 11:10
- 11:50 – 12:10 (Lunch)
- 13:10 – 13:40
- 15:15 – 15:45 (Power Hour / Final macros)

In the **last hour of trading** (e.g. 15:00–16:00 for indices), there are **4 macros every 15 minutes**.

Profile

More

1. Fractal Nature

Macros work on **any timeframe**. A 15M macro raid looks identical in logic to a daily macro raid - faster. You can scalp inside a 5M macro or swing inside a daily one.

2. PD Arrays

The highest-probability moments for price to **raid or respect** a PD Array (Order Block, FVG, Bre etc.) are **during a macro window**.

Institutions wait for these scheduled times to enter large orders without slippage.

3. SMT Divergence

SMT often **resolves or confirms** right at the start of a macro. One pair raids liquidity while the correlated pair respects the PD Array — classic macro behavior.

4. Weekly / Daily Profiles

The manipulation phase (Monday hover, Tuesday low, etc.) almost always ends or accelerates i **specific macro**.

Example: Classic Tuesday Low of the Week frequently forms during the 09:50–10:10 or London

5. Kill Zones

Macros **amplify** Kill Zones. London Open Kill Zone + London Macro = fireworks. NY Open Kill Zc 09:50–10:10 macro = one of the cleanest setups in all of ICT.

scalperintel.com

How Professional ICT Traders Actually Use Macros (Practical Rules)

TheRocketMan 
@yeobuzzfx

...

- **Never chase** outside a macro unless you have extreme confluence.
- **Best setups:** HTF PD Array + Weekly Profile bias + Macro Window + lower-TF displacement/FV/ SMT confirmation.
- Enter **after** the macro starts (usually 1–5 minutes in) on a lower-timeframe confirmation.
- Targets: Opposite liquidity or next PD Array (macros often deliver the full move in 10–40 minute
- Avoid trading **between** macros in low-volume periods (e.g. 11:10–11:50) unless in a strong trend.

Example of a perfect macro setup (common in 2024–2025 mentorship breakdowns):

09:50–10:10 NY macro → price raids sell-side liquidity in a **bearish PD Array (premium zone)** on the while showing bearish SMT vs correlated pair → short entry on the 5M FVG fill → quick 20–50 pip n

Macros are the reason many ICT traders say:

“Price and Time” — the time part was always the missing link until these were taught.

This completes the full picture: **Fractal structure + PD Arrays + SMT + Profiles + Macro Timing** = t complete institutional roadmap

 Ask anything

- Break down a **specific macro** (e.g. 9:50–10:10) with entry rules
- Explain how macros work with **Silver Bullet** or **Judas Swing**

...just tell me the pair or the exact setup you're curious about. I can also give you the exact macro tin your timezone.

Trading is probabilistic — backtest these windows heavily on demo first. Let me know how you wan apply this next!
